Critics have long faulted the widespread practice of trade promotions as wasteful. It has been estimated that this practice adds up to $100 billion worth of inventory to the distribution system. Yet, the practice continues. In this paper, we propose a price discrimination model of trade promotions. We show that in a distribution channel characterized by a dominant retailer, a manufacturer has incentives to price discriminate between the dominant retailer and smaller independents. While offering all retailers the same pricing policy, price discrimination can be implemented through trade promotions because they induce different inventory-ordering behaviors on the part of retailers.

Differences in inventory holding costs have been shown to be an important determinant of consumer promotions. Our analysis suggests that differences in holding costs are also potentially an important driver for the use of trade promotions. The implications from our model explain a number of anecdotal and/or empirically observed puzzles about how trade promotions are practiced. For example, our analysis explains why chain stores welcome trade promotions but independents do not. Our analysis outlines implications for managing trade promotions.

Key words: channels of distribution; channel power; trade promotion; forward buying

History: This paper was received April 5, 2006, and was with the authors 6 months for 2 revisions; processed by J. Miguel Villas-Boas. Published online in Articles in Advance July 31, 2008.

1. Introduction

According to the most recent estimate, consumer goods manufacturers in the United States spend about $85 billion on trade promotions, amounting to 13% of sales. In comparison, consumer promotions account for 6%, and advertising and media spending only 4% of sales (Cannondale Associates 2002). Although trade promotions are widely used by manufacturers, they are often seen as wasteful. For example, Buzzell et al. (1990) argue that trade promotions impose severe administrative burdens on manufacturers and add huge inventory costs to distribution channels. Many have asked the question: If trade promotions are inefficient, why are manufacturers still using them? A number of explanations have been proposed in the literature. It has been suggested that manufacturers face a Prisoners Dilemma-like situation—they have to offer trade promotions, otherwise the competition will take business away from them (e.g., Drèze and Bell 2003). Lal (1990) shows that national brand manufacturers could use trade promotions to limit the encroachment from a store brand. Lal et al. (1996) suggest that allowing retailers to forward buy benefits competing manufacturers because forward buying decreases the intensity of competition between manufacturers. Agrawal (1996) analyzes the role of brand loyalty in determining optimal advertising policy (defensive strategy to build brand loyalty) and trade promotion policy (offensive strategy to steal customers from competition).

In this paper, we offer another explanation for trade promotions. Our explanation essentially establishes the price discrimination role of trade promotions in a channel context. Manufacturers can use trade promotions to price discriminate between large retailers (e.g., chains) and small retailers (e.g., independents) by exploiting their different inventory carrying costs. Blattberg et al. (1981) have shown that retailers can take advantage of the differences in consumers’ inventory carrying costs. In this paper, we show that manufacturers can similarly take advantage of the differences in retailers’ inventory holding costs to achieve price discrimination through trade promotions.

However, price discrimination in a channel context is not a straightforward extension of that in a nonchannel context, as multiple channel members are now involved in pricing and inventory decisions. More importantly, this price discrimination explanation for trade promotions results in a number of interesting predictions that are consistent with some of the otherwise puzzling observations in the area of trade.

According to one estimate, $75–$100 billion worth of inventory is added into the U.S. distribution channel because of trade promotions. See Kahn and McAlister (1997, p. 21).
promotions. For example, the following predictions from our analysis explain why:

1. Manufacturers schedule their trade promotions well ahead to make it possible for retailers to plan forward buying.
2. Trade promotions are observed for packaged goods but not for perishable goods (Sellers 1992).
3. Chain stores are happier with trade promotions but independent and convenience stores are not.
4. Manufacturers allow forward buying but forbid diverting.
5. Manufacturers are complaining much more about trade promotions in recent years.

We believe that our ability to explain all these in the context of a parsimonious model suggests that the model is potentially useful. More specifically, in the context of a channel consisting of a single manufacturer and multiple retailers, we show that a manufacturer can effectively price discriminate among retailers by offering trade promotions if retailers have different inventory holding costs. The stores with lower holding costs and higher warehouse capacity (usually dominant retailers like chain stores and warehouse clubs) can benefit from forward buying. Interestingly, we further show that not only does the retailer with low holding costs benefit from trade promotions, but the retailer with high holding costs can also benefit from this practice. Indeed, social welfare can also increase. Although we initially derive these results in a dominant retailer channel setting (Samuelson and Nordhaus 1989), we show in the Technical Appendix, which can be found at http://mktsci.pubs.informs.org, that these results hold in a more general competitive channel setting also.

To the extent that a manufacturer can use trade promotions to price discriminate between retailers, Jeuland and Narasimhan’s (1985) paper is closely related to our study. However, our research differs from theirs. In their model, the retailers are not making pricing decisions. We explicitly model retailers’ pricing decisions over time. Our model therefore takes the Jeuland and Narasimhan’s (1985) analysis to the next logical step. This generalization yields interesting insights. One of these insights is that trade promotions can alleviate the double marginalization problem by giving the leading retailer more incentives to charge a lower retail price. In addition, the model allows us to make some testable predictions about the practice of trade promotions.

The rest of the paper is organized as follows. The next section describes the dominant retailer model. The analysis in §3 consists of two parts. The first part outlines the benchmark case, where the manufacturer is not allowed to offer trade promotions and analyzes the manufacturer’s incentives to price discriminate between a dominant retailer and the competitive fringe. The second part derives the manufacturer’s optimal trade promotion strategies and the retailers’ optimal pricing and inventory decisions. Section 4 derives a number of interesting predictions about the effect of trade promotions on the manufacturer’s profits, retailers’ profits, and social welfare. Section 5 relaxes some assumptions used in the model. We conclude with a summary in §6.

2. The Model
Consider a stylized channel where a manufacturer is selling a product through a dominant retailer (e.g., a chain store) and the competitive fringe (e.g., smaller independent retailers). The dominant retailer sets the retail price \( p \), and the competitive fringe takes the retail price as the market price (Samuelson and Nordhaus 1989). We start with the dominant retailer model for three reasons. First, the phenomenon of power retailers is a familiar scene in today’s retailing landscape, and large retailers are becoming independent and wholesalers who act as buying agents for independents always complain that trade promotions are not a fair practice for them (Zwiebach 1990, U.S. Distribution Journal 1992). For example, “Not surprisingly, in a broad survey of wholesalers, 87 percent agreed that the most urgent issue facing the wholesale-supplied system is fair and equal access to trade promotion funds” (U.S. Distribution Journal 1993b). On the other hand, chain stores benefit more from trade promotions and are happy with trade promotions (Progressive Grocer 2002, U.S. Distribution Journal 1993a). For instance, “Results also noted in the study show that wholesalers and their independent retail customers tend to benefit less from trade allowance programs than do other distribution channels” (U.S. Distribution Journal 1993a).

2 In Jeuland and Narasimhan (1985), a seller could price discriminate between more intensely consuming and less intensely consuming customers by offering temporary price cuts. To make this section consistent with the rest of the paper, we are using "manufacturer" and "retailers" as in the rest of paper to represent the "seller" and "customers" in Jeuland and Narasimhan (1985), respectively. We thank anonymous Reviewer 3 for the suggestion.

4 Double marginalization problem refers to the situation where the economic interests of upstream and downstream firms are not aligned, such that the retail price facing end-users is too high to maximize channel profits, as illustrated in Jeuland and Shugan (1985).

5 In Jeuland and Narasimhan (1985), a seller could price discriminate between more intensely consuming and less intensely consuming customers by offering temporary price cuts. To make this section consistent with the rest of the paper, we are using the price equals the (rising) marginal cost.
increasingly dominant in the marketplace.\(^7\)\(^8\) Second, large chains often assume the role of price leadership and exert pricing influence over smaller retailers (Raju and Zhang 2005). Third, the dominant retailer model simplifies the expositions considerably. As we show in the Technical Appendix, which can be found at http://mktsci.pubs.informs.org, if we were to relax the key assumption of only the dominant retailer setting the retail price and introduce price competition, our conclusions would not change qualitatively.\(^9\)

The total market demand in each period is given by

\[
Q = a - bp, \text{ where } a > 0 \text{ and } b > 0 \text{ are constants.}
\]

The demand facing the competitive fringe in each period is correspondingly,\(^10\)

\[
Q_c = Q - Q_d = (b_1 - b)p. \tag{2.2}
\]

In this dominant retailer channel, the competitive fringe’s demand is increasing in retail price \(p\), while the dominant retailer’s is decreasing in \(p\) such that these two different types of retailers do compete with each other. Figure 1 illustrates the demand functions

\[
Q_d = a - b_1 p. \tag{2.1}
\]

at the retail level. We assume \(b < b_1 \leq 3b/2\) in our analysis to avoid any corner solution.

In this channel, all retailers incur a holding cost for any inventory carried from one period to the next. In practice, chain stores and warehouse clubs usually have lower inventory costs than independents. One reason could be a lower cost of capital. Furthermore, chain stores and warehouse clubs also have higher inventory holding capacity and much more shelf space than independents, a big component of inventory holding costs, especially for food retailers (Blattberg et al. 1981). Therefore, it is reasonable to assume a lower inventory holding cost for the dominant retailer.\(^11\) We assume that the dominant retailer has a finite unit holding cost \((0 \leq h_1 < \infty)\) and retailers in the competitive fringe have an infinite unit holding cost \((h_2 = \infty)\). It is important to note that the infinite inventory holding cost for a competitive fringe is only a simplifying assumption, and we relax the assumption in the Technical Appendix, which can be found at http://mktsci.pubs.informs.org, where we allow a finite difference in the inventory holding costs between the dominant retailer and retailers from the competitive fringe. As the manufacturer’s production costs do not affect our substantive conclusions, we set them equal to zero for simplicity.

2.1. Manufacturer’s Decision Variables

The manufacturer in our model announces a wholesale price \(w_i\) for each period \(i\) within a pricing cycle

\[
\text{Figure 1 Retailers’ Demands for } b < b_1 \leq 1.5b
\]
2.2. Dominant Retailer’s Decision Variables
Conditional on the manufacturer’s decisions on the length of a pricing cycle \((N)\) and the wholesale prices in each period within the cycle \((w_1, w_2, \ldots, w_N)\), the dominant retailer sets the retail price \(p^i\) for periods \(i = 1, 2, \ldots, N\) to maximize its total profit in each pricing cycle. As the dominant retailer has a finite holding cost, some inventory may be carried from one period to the next if forward buying is profitable. Therefore, the dominant retailer also makes decisions on \(Q^i_d\), the inventory the dominant retailer orders in period \(i\) and sells in period \(j\), where \(i, j \in \{1, \ldots, N\}\) and \(i \leq j\).

Mathematically, the manufacturer solves the following optimization problem:

\[
\max_{w_1, w_2, \ldots, w_N} \left[ \sum_{i=1}^{N} w_i \left( \sum_{j=1}^{N} Q^i_d + Q^j_c \right) \right],
\]

where \(Q^i_d\) denotes the inventory the dominant retailer orders in period \(i\) and sells in period \(j\), and \(Q^j_c\) denotes the inventory the retailers in the competitive fringe order and sell in period \(i\). Of course, we have \(Q^j_c = 0\) for any \(i \neq j\), because a competitive fringe does not carry any inventory. Given the manufacturer’s wholesale prices and the length of pricing cycle \((w_1, w_2, \ldots, w_N, N)\), the dominant retailer’s optimization is given by

\[
\max_{p^1, p^2, \ldots, p^N, Q^i_d} \left[ \sum_{i=1}^{N} \sum_{j=1}^{N} p^j - w_i - h_1(i-1)Q^i_d \right].
\]

2.3. Competitive Fringe’s Decision Variables
Retailers in the competitive fringe take \(p^i\) as the market price in each period \(i\). As the holding cost for these retailers is assumed to be infinite, they do not carry any inventory from one period to the next. Therefore, a retailer in the competitive fringe will buy the product from the manufacturer and sell to customers if \(w_i \leq p^i\) in period \(i\).

We summarize the timing of decisions in this channel in Figure 2.

The model specified above can result in a number of different pricing outcomes. Figure 3 illustrates several possible optimal wholesale price schedules. We define trade promotions as temporary price discounts offered by the manufacturer to retailers. Therefore, all the schedules except Figure 3(a) could be viewed as trade promotion schedules. For instance, in Figure 3(b), \(w_1\) is the discounted wholesale price and \(w_2\) is the regular wholesale price. If the manufacturer offers a low price in one period and charges higher and increasing prices for the following two periods, as in 3(d), then \(w_1\) and \(w_2\) are both promotional wholesale prices, and \(w_3\) is the regular wholesale price.

3. Analysis
We first show why the manufacturer has an incentive to price discriminate. We analyze the manufacturer’s and the dominant retailer’s pricing decisions, assuming that the manufacturer charges a time-invariant single wholesale price to all retailers. This case of no trade promotions is our benchmark for comparison with the case where the manufacturer offers trade promotions to the retailers. We will show that under some conditions, trade promotions can increase the manufacturer’s profits as well as channel profits, even

---

\(^{12}\) In this paper, we are modeling off-invoice trade promotions.

\(^{13}\) For an early proof for the equivalence between maximizing average profit per period and maximizing total profit as discount factor approaches zero (see Jewell 1963).
after accounting for the additional inventory costs that are added into the channel as a consequence of forward buying by the dominant retailer.

3.1. Manufacturer’s Incentives to Price Discriminate Between Retailers

If the manufacturer does not offer trade promotions, i.e., that the wholesale price is constant over time, all retailers will order from the manufacturer in each period, and none will carry any inventory from one period to the next. The optimal prices and profits are easy to determine, and we simply state these in Lemma 1.

**Lemma 1.** If the manufacturer is restricted to offering a common time-invariant wholesale price to retailers, then the manufacturer will set its wholesale price at \( w = a(2b_1 - b)/2bb \), and the dominant retailer sets its retail price at \( p_1 = a(2b_1 + b)/4bb_1 \). The manufacturer’s average sales and profit per period are given by \( Q_1 = a(2b_1 - b)/4b_1 \) and \( \Pi_1 = a^2(2b_1 - b)^2/8bb_1^2 \), respectively.

**Proof of Lemma 1.** Please see Appendix B.14

Of course, a single wholesale price is suboptimal for the manufacturer for two reasons. First, the competitive fringe is passive in setting the retail price in the channel, and it will meet the residual demand as long as the wholesale price it has to pay is less or equal to the retail price set by the dominant retailer. Thus, ideally, the manufacturer wants to be able to charge the competitive fringe a higher wholesale price equal to the retail price, so as to take away all the profits from the competitive fringe. Second, the manufacturer must also be mindful of the double marginalization problem dissipating channel profits because of too high a retail price. Because only the dominant retailer’s marginal cost will determine the retail price, if possible, the manufacturer ideally wants to charge a lower wholesale price only to the dominant retailer. Therefore, to alleviate the double marginalization problem and to take advantage of the price-following behavior in the channel, it is in the manufacturer’s interest to price discriminate between the dominant retailer and the competitive fringe. However, charging different wholesale prices to different retailers who are competing in the same market is unlawful. The manufacturer must find some other mechanisms to reap the benefits of price discrimination. Trade promotions, or time-variant wholesale prices, is one such pricing mechanism.

3.2. Trade Promotions as a Mechanism to Price Discriminate

When the manufacturer offers trade promotions, it offers the same wholesale prices to all retailers. Thus, nominally, the manufacturer does not price discrim-

\[ w_i = \frac{N[4ab_1 - 2ab - b_1h_1(N - 1)]}{2b_1[b(N + 1) + b_1(N - 1)]} \]

\[ w_i = \frac{a + b_1w_1 + b_1h_1(i - 1)}{2b_1} \quad i = 2, \ldots, N \]

\[ p_i = \frac{a + b_1w_1 + b_1h_1(j - 1)}{2b_1} \quad j = 1, \ldots, N \]

\[ Q_{ai} = \frac{a - b_1w_1 - b_1h_1(j - 1)}{2} \quad j = 1, \ldots, N \]

\[ Q_{ci} = \frac{(b_1 - b)[a + b_1w_1 + b_1h_1(j - 1)]}{2b_1} \quad j = 1, \ldots, N \]

\[ \Pi_{hi} = \frac{1}{4b_1} \left[ 4ab_1 - 2ab - 2bb_1w_1 - bb_1h_1(N - 1) \right] \]

\[ w_i = p_i \quad i = 2, \ldots, N \]

\[ p_i - p_{i-1} = \frac{h_1}{2} \quad i = 2, \ldots, N \]
Figure 4 shows the manufacturer’s and the retailer’s optimal prices within a pricing cycle when \( N \) is equal to 5. The retail price will be raised by \( h_1/2 \) per period because the dominant retailer’s effective unit acquisition cost increases at the rate of \( h_1 \) per period.\(^\text{15}\) The manufacturer also raises the wholesale price by the same amount to take the surplus away from the competitive fringe. Thus, at any off-promotion period, the dominant retailer prefers to lower its price in the current period to sell more, instead of carrying any inventory forward to the next period. The manufacturer charges a wholesale price equal to the retail price in period \( i \) (\( i = 2, \ldots, N \)) to get all surplus from the competitive fringe. To determine the length of pricing cycle \( N \), the manufacturer solves the following optimization problem:

\[
\begin{align*}
\max_{N} & \quad \Pi_{h_1}(N) \\
\text{s.t.} & \quad w_i + (i - 1)h_1 \leq w_i, \quad i = 1, \ldots, N \\
& \quad w_1 = \frac{N[4ab_i - 2ab - b_1bh_1(N - 1)]}{2b_1[b(N + 1) + b_1(N - 1)]} \\
& \quad w_i = \frac{a + b_1w_1 + b_1h_1(i - 1)}{2b_1}, \quad i = 2, \ldots, N \\
& \quad N \geq 1.
\end{align*}
\]

(3.3)

The constraints \( w_i + (i - 1)h_1 \leq w_i \) guarantee that the dominant retailer’s effective unit acquisition cost of the items sold in period \( i = 2, \ldots, N \) is no higher than the wholesale price in the same period, so that the dominant retailer does not find it worthwhile to purchase from the manufacturer in period \( i \) at the current wholesale price. As the dominant retailer’s effective acquisition cost per unit is increasing at a faster rate \( (h_1 \text{ per period}) \) than the wholesale price \( (h_1/2 \text{ per period}) \) over time, there is an upper limit for \( N \) beyond which it is not profitable for the dominant retailer to carry any inventory. The constraints thus provide an upper bound on the manufacturer’s decision variable \( N \). As the range for \( N \) is convex and compact, there always exists a solution to the optimization problem (3.3). Given the optimal \( N \) and the sequence of wholesale prices preannounced by the manufacturer, retailers will not carry any inventory from one pricing cycle to the next, because the first period in the next pricing cycle will be a promotional period again. The manufacturer’s decisions on \( N \) and the sequence of wholesale prices in a pricing cycle will therefore not depend on its decisions in any other pricing cycles. In Appendix C, we show that the manufacturer’s announcement of both the length of pricing cycles \( N \) and the sequence of wholesale prices is credible. The manufacturer has no incentive in any period within a pricing cycle to deviate from the preannounced \( N \) and wholesale prices.\(^\text{16}\) This suggests that both the manufacturer’s and retailers’ behaviors are independent between pricing cycles.

It follows from the analysis above that the effective unit acquisition cost for the dominant retailer is lower than that for the competitive fringe in period \( i = 2, \ldots, N \), or \( w_i + h_1(i - 1) < w_i \) for \( i = 2, \ldots, N \). This leads to our first proposition.

**Proposition 1.** The manufacturer can use trade promotions to price discriminate between retailers who have different inventory holding costs.

Proposition 1 formally suggests a new justification for trade promotions not previously recognized in the literature. While offering the same wholesale price to all retailers but varying it over time, the manufacturer can price discriminate between retailers who are competing in the same market, as long as the retailer(s) with high wholesale price sensitivity has lower unit inventory holding costs than the retailer(s) with low wholesale price sensitivity. Because of the ability to price discriminate, the manufacturer can profit from trade promotions. This perhaps explains the paradoxical trend, as noted by Ailawadi et al. (1999, p. 84), that “at the peak of the trade promotion controversy, manufacturers’ profits increased at a fairly steady rate, whereas retailers’ profits were stable at best.”

Our analysis also sheds some light on why manufacturers typically allow forward buying, but vehemently oppose any diversion. Our analysis suggests that forward buying makes price discrimination

\(^{15}\) As we show in extensions, it is not necessary for wholesale prices to increase every period for the manufacturer to price discriminate between retailers. Two price points are sufficient for price discrimination to occur and allow the manufacturer to capture the bulk of the benefits from trade promotions.

\(^{16}\) We thank the Area Editor and anonymous Reviewers 1 and 4 for pointing out this to us. In practice, the manufacturer can also credibly commit to a sequence of prices because of reputation factors, legal factors, etc.
possible, but diversion weakens the price discrimination mechanism. Furthermore, Proposition 1 suggests that trade promotions could also alleviate the double marginalization problem. Therefore, the channel as a whole could benefit from such a practice because the manufacturer can induce the dominant retailer to set a lower retail price by charging the dominant retailer with a lower wholesale price—a lower retail price increases channel profits in a dyadic channel where the linear wholesale price contract is in use. Indeed, such benefits can be substantial, as we will show through numerical analyses in the next section.

4. Effects of Trade Promotions

A preliminary examination of the value of the price discrimination explanation for trade promotions can be made based on its ability to explain how trade promotions are practiced. To this end, we conducted numerical analyses to show the possible effects of trade promotions on players’ profits and social welfare. The results from the numerical analyses are limited in their generalizability but sufficient to motivate potential explanations for: (1) why trade promotions are frequently observed for packaged goods but rarely observed for perishable goods; (2) why chain stores are happy with trade promotions but independent and convenience stores are not; and (3) why manufacturers started complaining about the effectiveness of trade promotions as retailers became larger.

Table 1 lists the parameters used in the numerical study. We discuss our findings in detail in the following subsections.

4.1. Manufacturer’s Incentives to Offer Trade Promotions

Intuitively, all else being equal, the manufacturer will be more willing to offer trade promotions to retailers as a price discrimination mechanism if the dominant retailer has a lower unit holding cost. Furthermore, the incidence of trade promotions also depends on the size of the dominant retailer. All else being equal, if \( b_1 \) is smaller (\( b_1 \) closes to \( b \)), the manufacturer has less of an incentive to offer trade promotions because the dominant retailer is selling a bigger proportion of the total demand. The benefits from inducing the dominant retailer to charge a lower retail price will not offset the cost. If \( b_1 \) is larger (\( b_1 \) closes to \( 3b/2 \)), the manufacturer also has less of an incentive to offer trade promotions. This is because a larger \( b_1 \) gives the dominant retailer the incentive to charge a lower retail price, as a large \( b_1 \) implies a high consumer price sensitivity. Only for the intermediate values of \( b_1 \), the manufacturer will be willing to use trade promotions to price discriminate between the dominant retailer and the retailers in the competitive fringe. Figure 5 and Result 1 confirm these intuitions.

Result 1. Trade promotions can be profitable to the manufacturer when the dominant retailer’s unit holding cost \( h_1 \) is sufficiently low at any given \( b_1 \). At any given \( h_1 \), the manufacturer has incentives to offer trade promotions when the dominant retailer is sufficiently dominant but not overly dominant (\( b_1 \) is of an intermediate value).

Result 1 suggests that trade promotions are not always beneficial to the manufacturer. Only in those channel settings where the dominant retailer is not too dominant, or inventory holding costs vary sufficiently among retailers, are trade promotions beneficial to the manufacturer. This suggests that one is less likely to observe trade promotions in product categories, such as produce and frozen foods, where holding costs for these products are quite high and similar for both chain stores and independents. The easy-to-store items such as canned food or detergents, however, are expected to have more shipments on trade promotions.

Result 1 also suggests that the presence of a very dominant retailer (very low \( b_1 \)) in a distribution channel is not conducive to the functioning of trade promotions as a price discrimination mechanism. At any given inventory holding cost \( h_1 \), the more dominant the dominant retailer is in a channel, the less likely the manufacturer will resort to trade promotions. This suggests that one is less likely to observe trade promotions in product categories, such as toys and office supplies, where power retailers significantly dominate.

4.2. Effects of Trade Promotions on Sales  
A lower $h_1$ can facilitate price discrimination through trade promotions. Sales are therefore expected to increase with a smaller $h_1$. When the dominant retailer has a smaller $b_1$, or equivalently a larger demand share, the manufacturer will have a lower incentive to offer trade promotions. When $b_1$ is small, the double marginalization problem is worse, and sales do not increase as much.

Table 2 shows the percentage increase in the manufacturer’s sales by using multiple wholesale prices as opposed to the sales by using single wholesale price, i.e., $(Q_b - Q_s)/Q_s \times 100\%$, where $Q_s = a(2b_1 - b)/4b_1$ as shown in Lemma 1. This leads to the result below.

Result 2. Increase in average sales per period can decrease in the dominant retailer’s holding cost $h_1$ given $b_1$, and is increasing in the dominant retailer’s price-sensitivity parameter $b_1$, given $h_1$.

Result 2 and Table 2 suggest that when the manufacturer uses trade promotions to price discriminate between retailers, its sales can increase because of the reduced retail price, and such an increase is larger for a smaller $h_1$ and/or a larger $b_1$. As shown in Accenture (2001), 95% of the interviewed manufacturers cite “Increase Store Sales” as the top reason for trade promotions.17 Result 2 and Table 2 provide a potential rationale for such an almost unanimous citation from manufacturers about the reasons for trade promotions.

4.3. Effects of Trade Promotions on Profits  
As a lower $h_1$ facilitates price discrimination through trade promotions, the manufacturer’s profits are expected to increase with a smaller $h_1$.18 When the dominant retailer has a larger demand share (a smaller $b_1$), the profitability of trade promotions for the manufacturer is decreasing, as there is less surplus the manufacturer could take from the competitive fringe through price discrimination. Table 3 shows the percentage increase in the manufacturer’s profit by using multiple wholesale prices as opposed to a single wholesale price, i.e., $(\Pi_b - \Pi_s)/\Pi_s \times 100\%$, where $\Pi_s = a^2(2b_1 - b)^{2}/8bb_1^2$ as shown in Lemma 1. This leads to the result below.

Result 3. The increased profits from trade promotions as opposed to a single wholesale price for the manufacturer are decreasing in the dominant retailer’s holding cost $h_1$, and has an inverted-U relationship with the dominant retailer’s price-sensitivity parameter $b_1$.

Result 3 provides a potential rationale for the vocal complaints in recent years by the manufacturers about the effectiveness of trade promotions. As dominant retailers such as chain stores and warehouse clubs become larger (small $b_1$), the benefits of trade promotions to the manufacturer decrease. It is such a change that prompts some manufacturers to reevaluate the effectiveness of their trade promotions. From this perspective, it is easy to see why practitioners recognize that “success (of trade promotions) will be elusive unless independents are involved” and as far as the effectiveness of trade promotions is concerned, manufacturers “need a strong, viable independent sector” (Progressive Grocer Annual Report 2000, p. 30).

We can also examine how retailers’ profitability is affected by the same parameters $h_1$ and $b_1$. We summarize our results below.

Result 4. The benefits from trade promotions for the dominant retailer can decrease in its holding cost $h_1$ and have an inverted-U relationship with $b_1$. The competitive fringe retailers can become either worse off or better off because of trade promotions. Their gain from trade promotions can increase with $h_1$ and can have a U-shaped relationship with $b_1$.

---

17 The ACNielsen Report on Trade Promotion Practices (2004) shows a similar result: the top three reasons for manufacturers to run trade promotions are “increase sales volume,” “increase market share,” and “maintain current volume” that together account for 83% of responses.

18 Our numerical study shows that $N$ is decreasing in $h_1$, and increasing in $b_1$. 

---

Cui, Raju, and Zhang: A Price Discrimination Model of Trade Promotions
Intuitively, as the holding cost $h_1$ is a direct cost to the dominant retailer, a higher $h_1$ will reduce the dominant retailer’s profit. Our analysis shows that the increase in the dominant retailer’s profits has the highest value for the intermediate values of $b_1$ (Figure 6 in the Technical Appendix, which can be found at http://mktsci.pububs.informs.org, verifies this result). The intuition for this is as follows. The dominant retailer’s profits are affected by two factors. One is the average profit from each unit sold, and the other is the total number of units sold. When $b_1$ is large (close to $3b/2$), the manufacturer offers a higher promotional depth relative to the single-wholesale-price strategy (see Table 4) and the increase in the dominant retailer’s average profit from each sale as opposed to the single-wholesale-price strategy gets higher. However, for any $p$, its demand share is small for a large $b_1$. The effect of a small demand share dominates the effect of a high average profit from each sale; therefore, the dominant retailer’s profit is low for a large $b_1$. When $b_1$ is small (close to $b$), the dominant retailer has a large portion of demand, but the average profit from each sale is small because the manufacturer offers a higher $w_1$. Thus, the dominant retailer’s profits will again be small. Therefore, the dominant retailer’s profit is first increasing and then decreasing with $b_1$.

The numerical study also suggests that the pricing cycle will be shorter ($N$ is smaller) for a higher $h_1$. Because the first period within a pricing cycle is the only period during which the retailers in the competitive fringe can make a profit, they will have higher average profits with shorter pricing cycles, implying that the competitive fringe’s profit increases in $h_1$.

The competitive fringe gets the lowest profit for intermediate values of $b_1$ and more profits for smaller and larger $b_1$’s as expected. Also note that for a large $b_1$ and a large $h_1$, the competitive fringe could become better off because of trade promotions. For a given $b_1$, it is optimal for the manufacturer to choose a shorter pricing cycle when $h_1$ goes up. Thus, the promotional period 1, when the competitive fringe can get positive surplus, will occur more frequently as $h_1$ becomes larger and the competitive fringe becomes better off as a result. For a given $h_1$, the manufacturer will offer a lower $w_1$ but will choose a longer pricing cycle when $b_1$ becomes larger. When $b_1$ is very large, the positive effect of a lower $w_1$ on the competitive fringe’s profits will dominate the negative effect of a longer pricing cycle, and the competitive fringe

becomes better off. Therefore, the competitive fringe’s profit is first decreasing and then increasing in \( h_1 \).

4.4. Effects of Trade Promotions on Social Welfare

Many researchers have argued that trade promotions are harmful to a channel because of increased inventory holding costs. Although our model also suggests that trade promotions increase inventory holding costs, we find that trade promotions can potentially benefit the system as a whole by enabling the manufacturer to price discriminate between retailers. We state this result formally below (Figure 7 in Technical Appendix TB, which can be found at http://mktsci.pubs.informs.org, verifies this result).

Result 5. Trade promotions can increase social welfare. The increase in social welfare is smaller when the dominant retailer’s holding cost \( h_1 \) is larger or \( b_1 \) is smaller (or the dominant retailer is more dominant).

The source of the welfare improvement is the fact that price discrimination can alleviate the problem of double marginalization in the channel, to the benefit of not only the manufacturer and the retailers but also the consumers. Trade promotions induce the dominant retailer to choose a low retail price. Although the retail price goes up by \( h_1/2 \) per period because of the presence of the holding cost \( h_1 \), the retail prices in most periods will be lower than the benchmark retail price \( p_* = a(2b_1 + b)/4bh_1 \), the retail price that the dominant retailer would set if the manufacturer were to charge all retailers the same time-invariant wholesale price \( w_* = a(2b_1 - b)/2bh_1 \). Interestingly, competitive fringe may even benefit from trade promotions as shown above. This is because the channel profit increases as the double marginalization problem is lessened and all channel members, including the competitive fringe, can benefit from increased channel sales. Even when the competitive fringe becomes worse off because of price discrimination, the total social welfare can still increase because of the lower retail price set by dominant retailer. Consequently, trade promotions can improve channel efficiency and increase social welfare.

Overall, what emerges from Proposition 1 and Results 1–5 is a different perspective on trade promotions. Manufacturers embrace trade promotions because the practice allows them to implement price discrimination in a distribution channel. In light of this perspective, it is rather understandable that when manufacturers run trade promotions, they allow forward buying but disallow diversion. Our model can also explain why retailers do not all endorse this practice. The dominant retailer favors such a practice because it stands to benefit from trade promotions because of its low inventory holding costs. The competitive fringe could oppose such a practice because it would become worse off because of the effective price discrimination that trade promotions achieve. However, this does not mean that such a practice is harmful because social welfare can increase with this practice. Finally, manufacturers might have incentives to abandon this practice as the retail consolidation continues.19

5. Extensions

Our basic model leaves the following three important questions unanswered so far:

(1) Does price discrimination necessarily require multiple wholesale prices, as suggested by the solution to the optimization problem (3.3)? If it does, such a theory would be rather counterfactual because in practice, we often observe manufacturers alternating between two wholesale prices in a given period of time: the regular and discounted wholesale prices.

(2) Does a price-discrimination explanation of trade promotions also hold in the situations where the competitive fringe has finite (as oppose to infinite) inventory holding costs?

(3) Does the price discrimination explanation of trade promotions depend on the assumption of dominant retailer channel (i.e., only the dominant retailer has pricing power)? In other words, if the competitive fringe independently and competitively sets its retail price, would the manufacturer’s incentives to use trade promotions to price discriminate go away?

5.1. Comparing the Two-Price Model with the Full Model

In our basic model, as the optimal solution, the manufacturer’s wholesale price increases every period, after the initial dip, over the rest of the pricing cycle. This feature of our solution is not necessary because two price points are sufficient for price discrimination to occur. In fact, there are three ways to reconcile our optimal solution with the frequently observed trade promotion practice of two price points. First, the parameters can be such that the optimal solution calls for a regular wholesale price and a discounted price. In other words, there is a possibility that a two-price solution might indeed be optimal. Of course, such an explanation would be, admittedly, quite tenuous, given that our model does not offer a way to restrict the parameter space.

19This might well explain why the portion of trade promotion budgets allocated to off-invoice allowances has decreased from about 90% in the mid-1990s to about 35% in recent years (Cannondale Associates 2003), but chain retailers, as they become more dominant through consolidation, prefer off-invoice trade promotions to performance-based promotions such as scan-backs. Gómez et al. (2005) find that retailers with a larger share of private label, larger annual sales, and stronger brand positioning do demand more trade promotion funds to off-invoices.
Second, we show that using only two price points allows the manufacturer to price discriminate between the dominant retailer and competitive fringe effectively and to capture the bulk of the benefits from trade promotions. When the manufacturer is restricted to adopt the two-wholesale-price strategy only, all results under the multiple-wholesale-price strategy will hold! This means that this practice can also be justified based on the trade-off between simplicity in administering trade promotions and profit gains. As Table 5 shows, the profit that the manufacturer sacrifices when switching from a regime of unconstrained multiple wholesale prices to a regime of constrained two wholesale prices is small (smaller than 1%). This implies that even with the minimalist approach of two price points, the manufacturer can reap substantial benefits from trade promotions.

Finally, it is assumed that price changes are costless. In practice, cost of changing prices can be substantial, both in terms of monetary costs and in terms of goodwill (Levy et al. 1997). When such a cost is considered, the manufacturer might want to use two price points.

5.2. Finite Inventory Holding Costs for Both Retailers

If the competitive fringe has a finite (as opposed to infinite in the basic model) unit inventory holding cost, but such cost is still higher than the dominant retailer’s (i.e., \( 0 < h_1 < h_2 < \infty \)), the manufacturer can still use trade promotions to price discriminate. The proofs are in the Technical Appendix, which can be found at http://mktsci.pubs.informs.org. The price discrimination comes about because of the extent to which different retailers can take advantage of trade promotions because of differences in holding costs.

5.3. Generalizing from the Dominant Retailer Model

Consider, for instance, an alternative demand model given by

\[
Q_1 = a_1 - b_1 p_1 + c_1 p_2,
\]

\[
Q_2 = a_2 - b_2 p_2 + c_2 p_1,
\]

where \( p_i \) is the price for retailer \( i \) (Sayman et al. 2002). In Technical Appendix A, which can be found at http://mktsci.pubs.informs.org, we show that in this model, the manufacturer can price discriminate between retailers through trade promotions, even if both retailers independently and simultaneously make pricing decisions, as long as \( \min(b_1, b_2) > \max(c_1, c_2) \). In other words, as long as the competing retailers exhibit different price sensitivities to the wholesale price, and the higher price-sensitivity retailer has a lower inventory holding cost, the manufacturer can benefit from price discrimination through trade promotions.

6. Conclusion and Discussion

Many researchers have argued that trade promotions are harmful to manufacturers and to the distribution channel because of the added inventory-holding costs. Using a dominant retailer model, we show that trade promotions can benefit manufacturers and the channel precisely because of the added inventory cost: these costs provide the manufacturers with an opportunity to price discriminate between a dominant retailer and the competitive fringe. We show that the price discriminating function of trade promotions is not specific to the dominant retailer model and works for other competitive models also.

What this analysis implies is that manufacturers might want to proceed cautiously to rein in the practice of trade promotions. At the minimum, they need to weigh the benefit of price discrimination against any possible increase in the inventory and production costs in making such decisions.

The price discrimination perspective also sheds some new light on the practice of trade promotions. At a more general level, our analysis explains a few otherwise puzzling sets of practices associated with trade promotions: manufacturers do not seem to complain about the effectiveness of trade promotions or want to take the initiative of abandoning the practice (or when they do, they suffer); manufacturers
allow forward buying but not diversion; power retailers urge for trade promotions, but small and independent retailers frequently condemn the practice as unfair. Our analysis shows that price discrimination implemented through trade promotions could favor the manufacturer and the dominant retailer at the expense of the competitive fringe, and effective price discrimination can be implemented if there is forward buying but no diverting on the part of the dominant retailer.

Our analysis also shows that price discrimination induced through trade promotions can be welfare-enhancing as it alleviates the problem of double marginalization in a distribution channel. We also show that trade promotions can increase social welfare, as the difference between retailers' holding costs is sufficiently large or the dominant retailer's market share is sufficiently small (\(b_1\) is large). Surprisingly, our analysis also finds that trade promotions might also benefit the competitive fringe under some conditions. The benefits to the competitive fringe come during promotional periods, in which all retailers enjoy the low wholesale price. Thus, when the dominant retailer has a high holding cost \(h_1\) and a low market share (large \(b_1\)), the manufacturer will promote frequently with a high promotion depth to the benefit of the competitive fringe.

Our analysis suggests that one is more likely to observe trade promotions in industries or product categories where inventory holding cost is sufficiently small, or power retailers are not too dominant. These are testable predictions.

One could argue that trade promotions as a price discrimination mechanism are potentially more effective and robust than other pricing mechanisms such as quantity discounts or a menu of two-part tariffs (Kuksov and Pazgal 2007). For instance, when a manufacturer uses quantity discounts to price discriminate against small retailers, the small retailers may be able to get together and pool their purchases to avail themselves of a low wholesale price. They can act similarly under a menu of two-part tariffs. However, with trade promotions, the competitive fringe retailers need to invest in joint warehouse facilities to be able to take advantage of periodic price deals. Said differently, as a price discrimination mechanism, trade promotions generate potentially less leakage than other posted price mechanisms.

While we believe that our analysis has generated some interesting new insights, it is important to point out the limitations of our model. In our model, we do not explicitly model product differentiation, although a downward-sloping demand curve for the dominant retailer does suggest some differentiation in its offerings. If the retailers in the competitive fringe can offer vertically differentiated products to customers, we suspect that the competitive fringe will have more power and can be more profitable compared with the current model.\(^{20}\) We do not consider the manufacturer’s holding costs in the model. If the manufacturer has to hold inventory instead of transferring all inventory to retailers and has lower inventory holding costs than retailers, will trade promotions still benefit the channel? We suspect that trade promotions can still be beneficial, as the motivation for and the effects of price discrimination in a channel do not go away because of a lower inventory holding cost on the part of the manufacturer. We also assume that the manufacturer is selling a single product through retailers. In a multiple-product setting, studies on how trade promotions on one product affect the profits of other products might generate additional insights (Chen and Xie 2007). Finally, we assume that the manufacturer is a monopoly in supplying products to retailers (Liu and Zhang 2006). It is important for future research to investigate whether trade promotions could still help manufacturers to price discriminate between retailers in a competitive context. We suspect that they still could, because competition rarely negates any incentive for price discrimination.

Acknowledgments

Appendix A. Retailers’ Incentives to Reduce Holding Costs
Assume \(0 < h_1 \leq h_2 < \infty\). The manufacturer will offer a wholesale price \(w_1\) in the first period and \(w_i\) in period \(i\). Furthermore, it will charge a \(w_i\) and choose a pricing cycle length \(N\) such that the competitive fringe will not make bridge buying, otherwise the manufacturer will offer a single wholesale price \(w_s\), instead of offering a trade promotion with both retailers making bridge buying. Intuitively, the dominant retailer, who is making bridge buying, will have a larger incentive to reduce unit holding cost because the dominant retailer will reduce unit acquisition cost in each of the \(N\) periods. The competitive fringe, who has a unit holding cost \(h_s > h_1\) and is making forward buying for a shorter period than \(N\), will have a smaller incentive because it will benefit from reduced holding cost in less than \(N\) periods. We formally prove this result below.

Dominant Retailer’s Incentives
Given \(w_i\) and \(N\), the dominant retailer will choose a retail price \(p_i = \frac{(\alpha + h_s w_i + b_i h_1 (i-1))}{2b_i}\) in period \(i\) and its effective unit acquisition cost in period \(i\) will be equal to \(w_i + (i-1) h_1\), \((i = 1, \ldots, N)\). Therefore, the dominant retailer’s profit in period \(i\) is given by

\[
\pi^*_i = [p_i - w_i - (i-1) h_1](\sigma - b_i p_i), \quad (A1)
\]

\(^{20}\) We thank an anonymous reviewer for pointing out this issue.
and its total profit in one pricing cycle is given by
\[ \pi^T_i = \sum_{i=1}^{N} \pi^T_{ij} = \sum_{i=1}^{N} \left[ p^i - w_1 - (i-1)h_1 \right] (a - b_i p^i). \] (A2)

The dominant retailer’s incentive to reduce holding cost \( h_1 \) is therefore given by\(^{21}\)
\[ \frac{\partial \pi^T_i}{\partial h_1} = \sum_{i=1}^{N} \frac{\partial \pi^T_{ij}}{\partial h_1} = -\sum_{i=1}^{N} (i-1) (a - b_i p^i) = -\sum_{i=1}^{N} (i-1) Q_{di} < 0. \] (A3)

That is, the dominant retailer’s profit will be higher as its holding cost \( h_1 \) goes down.

**Competitive Fringe’s Incentives**

We have stated that the retailers in the competitive fringe are not making bridge buying as the dominant retailer is. Otherwise, trade promotions will not be profitable for the manufacturer. However, the competitive fringe’s non-infinity unit holding cost \( h_2 \) makes it probable for the competitive fringe to make forward buying in the promotional period. Let \( \bar{x} \) be the number of periods in which the competitive fringe’s effective unit acquisition cost in period \( i = 1, \ldots, \bar{x} \) is lower than the retail price \( p^i \) if the competitive fringe makes forward buying in the first period at the wholesale price \( w_1 \). That is, \( w_1 + (\bar{x} - 1) \cdot h_2 < p^i \) and \( w_1 + (\bar{x} + 1 - i) h_2 > p^i > 1. \) Knowing the competitive fringe’s effective acquisition cost, the manufacturer will not charge the retailers in competitive fringe a wholesale price equal to \( p^i \) in periods 1 to \( \bar{x} \), but charge them the effective unit acquisition cost \( w_1 + (i-1) h_2 \) to make competitive fringe retailers indifferent between making forward buying and ordering from the manufacturer in each period. Because the effective unit acquisition cost is not lower than the promotional price \( w_1 \), the manufacturer could have higher profits by charging them the effective acquisition cost than announcing a wholesale price equal to the retail price in period \( i = 1, \ldots, \bar{x} \). Assume \( x \) makes the constraint equal
\[ w_1 + (x-1) h_2 = p^i = \frac{a + b_i w_1 + b_i h_1(x-1)}{2b_i}, \] (A4)

and we get \( x = 1 + (a - b_i w_1)/(b_i(2h_2 - h_1)) \). Therefore, we have
\[ \bar{x} = \text{int}[x] = \text{int} \left[ 1 + \frac{a - b_i w_1}{b_i(2h_2 - h_1)} \right] \text{ and } x - 1 < \bar{x} \leq x. \] (A5)

Assume there are \( C \) identical retailers in the competitive fringe, each of whom has a demand proportion of \((1/C)Q_{ci} = (1/C)(b_1 - b)p^i\) in period \( i = 1, \ldots, N \). Any retailer’s effective unit acquisition cost of each item sold in period \( i \leq \bar{x} \) equals \( c^i = w_1 + (i-1) h_2 \), and the retailer’s profit in period \( i \) is given by
\[ \bar{\pi}^i = \sum_{i=1}^{N} \bar{\pi}^T_{ij} = \sum_{i=1}^{N} (p^i - w_1 - (i-1)h_1) \frac{b_i - b}{C} p^i. \] (A6)

The retailer’s profits from period \( \bar{x} + 1 \) to period \( N \) are zero because the manufacturer will take all surplus from the competitive fringe by charging a wholesale price slightly lower than the market price. So the total profit within a pricing cycle for any retailer in competitive fringe is given by
\[ \pi^T_{ci} = \sum_{i=1}^{\bar{x}} \bar{\pi}^T_{ij} = \sum_{i=1}^{\bar{x}} (p^i - w_1 - (i-1)h_2) \frac{b_i - b}{C} p^i. \] (A7)

The incentive for any retailer in the competitive fringe to reduce holding cost \( h_2 \) is given by
\[ \frac{\partial \pi^T_{ci}}{\partial h_2} = \sum_{i=1}^{\bar{x}} \frac{\partial \pi^T_{ij}}{\partial h_2} = -\sum_{i=1}^{\bar{x}} (i-1) \frac{b_i - b}{C} p^i = -\sum_{i=1}^{\bar{x}} (i-1) \frac{1}{C} Q_{di} < 0. \] (A8)

That is, the competitive fringe’s profit will be higher as the holding cost \( h_2 \) goes down.

Because \( \bar{x} < N \), Equations (A3) and (A8) show that the dominant retailer has more incentives than any competitive fringe to reduce holding costs if the dominant retailer’s demand \( Q_{di} \) is not smaller than the demand of any retailer in the competitive fringe \(((1/C)Q_{ci})\) in periods \( i = 1, \ldots, \bar{x} \), or \( \sum_{i=1}^{\bar{x}} (i-1) (a - b_i p^i) > \sum_{i=1}^{\bar{x}} (i-1)(b_1 - b)/C) p^i \) for \( Q_{di} \geq (1/C)Q_{ci}. \)

**Appendix B. Proof of Lemmas and Proposition 1**

**Proof of Lemma 1.** Conditional on wholesale price \( w_1 \), the dominant retailer’s profit in any period is given by
\[ \pi_{d,s} = (p_s - w_1)(a - b_i p_s). \] (B1)

The first-order conditions (FOC) of the profit function determines the dominant retailer’s optimal retail price, which is given by
\[ p_s = \frac{a + b_i w_1}{2b_i}, \] (B2)

and retailers’ demands are given by
\[ \begin{align*}
Q_{d,s} &= a - b_i p_s = \frac{a - b_i w_1}{2} \\
Q_{c,s} &= (b_1 - b) p_s = \frac{(b_1 - b)(a + b_i w_1)}{2b_i}.
\end{align*} \] (B3)

The manufacturer chooses \( w_1 \) to maximize its profit \( \Pi_s = w_1(Q_{d,s} + Q_{c,s}) \). The optimal \( w_1 \) is given by
\[ w_1 = \frac{a(2b_1 - b)}{2bb_1}. \] (B4)

Given \( w_1 = a(2b_1 - b)/2bb_1 \), it is easy to derive other results in the lemma. □
Proof of Lemma 2. The way to prove Lemma 2 is to consider the dominant retailer’s decisions in an arbitrary period based on effective unit acquisition cost. The dominant retailer purchases inventory in the first period at a wholesale price \( w_0 \) and will be charged a unit holding cost \( h_1 > 0 \) per period for inventory it carries from one period to the next. Thus the effective unit acquisition cost of the units sold in period \( j = 1, \ldots, N \) is equal to \( w_j + (j - 1)h_1 \). Here, \( w_j \) is the original purchase cost and \( (i - 1)h_1 \) is the holding cost charged to each unit sold in period \( i \). Therefore, the dominant retailer’s profit for period \( j \) is given by

\[
\pi_{d,j} = [p^j - w_j - (j - 1)h_1](a - b)p^j, \quad (B5)
\]

and it will choose a retail price \( p^j = (a + b_1w_j + b_1h_1(j - 1))/2h_1 \) in period \( j \). Both the dominant retailer and the competitive fringe pay the promotional wholesale price \( w_j \) in the first period. From the second period on, the manufacturer will charge the competitive fringe a wholesale price equal to the retail price \( p^j \) as given in any period \( j \). That is, \( w_j = p^j \) for \( j = 2, \ldots, N \).

The manufacturer’s average profit per period in a pricing cycle is given as follows:

\[
\Pi_{h_1} = \frac{1}{N} \left[ \sum_{i=1}^{N} (a - b)p^i + w_1(b_1 - b)p^1 + \sum_{j=2}^{N} w_j(b_1 - b)p^j \right], \quad (B6)
\]

where \( \sum_{i=1}^{N} (a - b)p^i \) is the dominant retailer’s total ordering quantity, \( p^i = (a + b_1w_i + b_1h_1(i - 1))/2h_1 \) is the retail price in period \( i \), and \( w_j = p^j \) is the wholesale price in period \( j = 2, \ldots, N \). Because \( \Pi_{h_1} \) is strictly concave in \( w_j \), FOC solves \( w_j \) as follows:

\[
w_j = \frac{N[4ah_j - 2ab - bb_1(N - 1)]}{2b_1[N(N + 1) + b_1(N - 1)]}. \quad (B7)
\]

Other results in Lemma 2 can then be easily derived. □

Proof of Proposition 1. If \( 0 \leq h_1 < h_2 = \infty \), the manufacturer will offer wholesale prices \( w_i \) and \( w_j \) (\( i = 2, \ldots, N \)) as in Equation (3.1). For items sold in the promotional period, both the dominant retailer and competitive fringe are having the same unit acquisition cost \( w_i \). For items sold in period \( i = 2, \ldots, N \), the unit acquisition cost for the dominant retailer is equal to \( w_i + h_i(i - 1) \) and the cost for the competitive fringe is equal to the wholesale price in that period \( w_i = (a + b_1w_i + b_1h_1(i - 1))/2h_1 \). We have \( w_i - [w_1 + h_1(i - 1)] = (a - b_1[w_i + h_1(i - 1)])/2h_1 = (a - b_1p^j)/h_1 > 0 \). Therefore, the competitive fringe is paying a higher average unit acquisition cost in a pricing cycle than the dominant retailer. If \( 0 \leq h_1 < h_2 < \infty \), the same logic still applies as long as the optimal pricing cycle length is \( N \geq 2 \). The only difference is that it is possible that the retailers in the competitive fringe would also like to carry some inventory from one period to the next, but they will carry items for fewer periods than the dominant retailer because of their higher inventory holding cost. If they are carrying items for the same periods as the dominant retailer, trade promotions will not be worthy of the manufacturer and the optimal \( N \) will be equal to 1, i.e., no trade promotions are offered. □

Appendix C. Credibility of Manufacturer’s Announcement of \( N \) and \( w_i \) (\( i = 1, \ldots, N \))

In this section, we will show that the manufacturer’s announcements of both the length of pricing cycle \( N \) and the wholesale price \( w_i \) for each period \( i \) within a pricing cycle consisting of \( N \) periods (\( i = 1, \ldots, N \)) are credible. That is, given the announced \( N \) and \( w_i \) (\( i = 1, \ldots, N \)) determined as in Lemma 2, the manufacturer will not have incentives to deviate from them. The intuition is as follows. Given the preannounced optimal \( N \), the manufacturer will not have incentive to extend \( N \) to any \( \tilde{N} > N \). The reason for the manufacturer to run trade promotions is that trade promotions will provide a higher average profit per pricing cycle for the manufacturer than a time-invariant wholesale price. If a manufacturer deviates from \( N \) to \( \tilde{N} > N \) and charges the optimal time-invariant wholesale price \( w_i \) as shown in Lemma 1 for periods \( N + 1, \ldots, \tilde{N} \) (the dominant retailer’s inventory ordered in period 1 will be depleted in period \( N \)), the manufacturer will get a lower average profit per period for periods \( N + 1, \ldots, \tilde{N} \). Given the preannounced \( N \), the manufacturer will have no incentive to deviate to any \( \tilde{N} < N \) either. In a pricing cycle, the manufacturer gets a much lower profit from units sold in period 1 than the average profit per period in the pricing cycle since the wholesale price \( w_1 \) is low and available to both the dominant retailer and competitive fringe. In each period \( i \) (\( i = 2, \ldots, N \)), however, the manufacturer will get a higher than average profit from units sold in period 1 than the average profit per period in the pricing cycle since the wholesale price \( w_1 \) is low and available to both the dominant retailer and competitive fringe. In each period \( i \) (\( i = 2, \ldots, N \)), however, the manufacturer will get a higher than average profit from units sold in period 1 than the average profit per period in the pricing cycle since the wholesale price \( w_1 \) is low and available to both the dominant retailer and competitive fringe. Therefore, the manufacturer will have no incentive to either extend or shorten a pricing cycle from \( N \) to any \( \tilde{N} > N \) or \( \tilde{N} < N \). In any period \( i = 2, \ldots, N \), the manufacturer will have no incentive to deviate from the preannounced \( w_i \) either. Because \( w_i = p^i \) for \( i = 2, \ldots, N \), the manufacturer will not increase the wholesale price because such an increase will let the manufacturer lose the profit from competitive fringe by making the wholesale price for the competitive fringe higher than the retail price. The manufacturer will also have no incentive to decrease wholesale price. If the reduced wholesale price in any period \( i = 2, \ldots, N \) (denoted as \( \tilde{w}_i \)) is so low that the dominant retailer finds it profitable to make an order, it is equivalent to the case where the manufacturer starts a new pricing cycle (equivalently, chooses an \( \tilde{N} < N \)), which is not optimal for the manufacturer as shown above. If the reduced wholesale price is not low enough to induce the dominant retailer to order in period \( i = 2, \ldots, N \), the manufacturer will lose a margin of \( w_i - \tilde{w}_i \) from competitive fringe, which is also not optimal. Either way, the manufacturer will not get a higher profit by deviating from the preannounced \( w_i \). Thus, the manufacturer will not deviate from the preannounced \( N \) and \( w_i \) (\( i = 1, \ldots, N \)).
show that the manufacturer will not have incentives to deviate from wholesale price \( w_i \) for each period \( i \) within a pricing cycle consisting of \( N \) periods \( (i = 1, \ldots, N) \), given the dominant retailer’s order in the first period \( Q_{i1} = \sum_{i=1}^{N} Q_{ii} = (N/4)[2(a - b) \bar{w}_i] - b_1 h_1 (N - 1) \).

No Deviation from \( N \)

Given both dominant retailer’s and competitive fringe’s decisions in Lemma 2, the manufacturer will not increase the length of pricing cycle from the optimal \( N \) to any \( \bar{N} \) for \( N < \bar{N} < 2N \).\(^{22}\) Suppose the manufacturer changes the length of pricing cycle from \( N \) to \( \bar{N} \) after the dominant retailer makes its order in the first period

\[
Q_{\bar{N}}^1 = (N/4)[2(a - b) \bar{w}_i] - b_1 h_1 (N - 1) .
\]

It is then optimal for the manufacturer to set a wholesale price at \( w_i = a(2b_i - b)/2bb_i \), for each period \( j \) \( (j = N + 1, N + 2, \ldots, \bar{N}) \) and gets an average profit per period of \( \Pi_j^i = a^2(2b_i - b)^2/8bb_i^2 \) for periods \( N + 1, N + 2, \ldots, \bar{N} \) if trade promotions are not used between periods \( N + 1 \) and \( \bar{N} \).\(^{23}\) Because the reason for the manufacturer to provide trade promotions is that trade promotions will provide a higher average profit to the manufacturer than a common time-invariant wholesale price to retailers, it is not optimal for the manufacturer to deviate from \( N \) to any \( \bar{N} > N \). Now, let’s show that the manufacturer also has no incentives to shorten \( N \) to any \( \bar{N} < N \). To prove so, we need the following lemma, which shows that the manufacturer’s profit from sales in period \( N \) is the smallest among periods \( 2, \ldots, N \).

**Lemma 3.** In a pricing cycle, the manufacturer’s profit from sales in a period is the minimum in period \( j = \min[N, (bb_i \bar{w}_i - (b_i - b)(a - b)h_1)/h_1(b_i(b_i - b))] \) among periods \( 2, \ldots, N \).

**Proof of Lemma 3.** The sales in any period \( j = 2, \ldots, N \) consists of two parts—sales of the items the dominant retailer orders in period 1 at a wholesale price \( w_i \) and carries to period \( j \), and sales of the items the firms in competitive fringe order from the manufacturer at a wholesale price \( w_i \) and sell in period \( j \). The sales in period \( j \) is equal to \( Q_j = a - bp_i' = (2ab_i - ab - bb_i \bar{w}_i - bb_i h_1(j - 1))/2bb_i \), as shown in Lemma 2. Manufacturer’s profit from the sales in period \( j = 2, \ldots, N \) is thus given by

\[
\Pi_j^i = w_i Q_j + \sum_{i<j} Q_{ij} = w_i \left[ a - b \bar{w}_i - b_1 h_1(j - 1) \right]/2 + (b_i - b)[a + b_i \bar{w}_i + b_1 h_1(j - 1)]/4bb_i^2 . \tag{C1}
\]

\(^{22}\) If \( \bar{N} \geq 2N \), then the focal periods we focus on will be from period \( i_o = N \) to period \( \bar{N} \), where \( i_o = \text{int}[\bar{N}/N] \). We will then get similar insights as the case, when \( N < \bar{N} < 2N \).

\(^{23}\) An alternative way is for the manufacturer to use trade promotions to price discriminate between retailers between periods \( N + 1 \) and \( \bar{N} \), but such a shorter pricing cycle will be suboptimal compared with the optimal pricing cycle with a length of \( N \) because the optimal \( N \) is determined such that it profit dominates any other length of pricing cycle (see Problem (3.3)).

The derivatives of \( \Pi_j^i \) with respect to \( j \) are given by

\[
\begin{align*}
\frac{d\Pi_j^i}{dj} &= \frac{h_1(a(b_i - b) + b_1 h_1(b_i - b)(N - 1) - bb_i \bar{w}_i)}{2bh_1} \\
\frac{d^2\Pi_j^i}{dj^2} &= \frac{h_i^2(b_i - b)^2}{2} > 0.
\end{align*}
\]

Because the twice derivative of \( \Pi_j^i \) with respect to \( j \) is positive, \( \Pi_j^i \) is strictly convex in \( j \). Therefore, the manufacturer’s profit \( \Pi_j^i \) from sales is minimum in period \( j = \min[N, (bb_i \bar{w}_i - (b_i - b)(a - b)h_1)/h_1(b_i(b_i - b))] \) among periods \( 2, \ldots, N \), where \( (bb_i \bar{w}_i - (b_i - b)(a - b)h_1)/h_1(b_i(b_i - b)) \) is solved from the FOC of \( \Pi_j^i \). □

When the manufacturer offers trade promotions in period 1, the promotional wholesale price \( w_i \) is the same as period 2, but will be carried over to and sold in the new pricing cycle. The higher-than-average profit in period 1 is smaller than the average profit under constant wholesale price \( \Pi_i \). Thus, the manufacturer’s profit from items sold in period 1 is smaller than the average profit in a pricing cycle. Starting from period 2, the manufacturer will have to get a higher profit from the items sold in each period than the average profit to compensate the profit loss in period 1. This will generate a smaller average profit per period in a pricing cycle.

Table C.1 shows, numerically, that the manufacturer’s profit in period

\[
\min[N, (bb_i \bar{w}_i - (b_i - b)(a - b)h_1)/h_1(b_i(b_i - b))]
\]

is always larger than its average profit per period in the pricing cycle when the manufacturer chooses to offer trade promotions.

\(^{24}\) Numerical study shows that within the wide parametric ranges \( d\Pi_i^i/dj \) is negative for \( j = N \). That is, the manufacturer’s average profit in each period among periods \( 2, \ldots, N \) is decreasing in \( j \) for the studied parametric values.

\(^{25}\) The manufacturer’s profit from items sold in period \( i \) by both retailers instead of its profit from items sold in period \( i \) by competitive fringe should be considered only here. This is because if the manufacturer truncates a pricing cycle at period \( i \), then the items that could have been sold by the dominant retailer in period \( i \) will be carried over to the new pricing cycle in an infinitely repeated game.
promotions to retailers. Therefore, the manufacturer has no incentive to truncate any pricing cycle into a pricing cycle with a length of $N < N$ because the period
\[
\min [N, (bb, w_i - (b_1 - b)(a - b_1 h_i)) / (b_1 h_i (b_1 - b))]\]
with the lowest average profit among periods $2, \ldots, N$ has a higher-than-average profit. That is, the announcement of optimal $N$ is credible and self-enforcing—the manufacturer will not deviate to any $N > N$ or $N < N$ in any period $i = 2, \ldots, N$ within a pricing cycle.

No Deviation from $w_i$
In this subsection, we will show that the manufacturer will not deviate from preannounced wholesale price $w_i$ in any period within a pricing cycle.

With the announced sequence of wholesale prices $w_i$ ($i = 1, \ldots, N$), the manufacturer will charge the lowest wholesale price in period 1 to induce the dominant retailer to make forward buying. From period 2 until period $N$, the manufacturer will charge a wholesale price equal to retail price in each period to take full surplus from competitive fringe. In any period $i = 2, \ldots, N$, the manufacturer will not increase the wholesale price $w_i$ to any larger price because such an increase will make the wholesale price higher than the retail price, and thus the manufacturer will lose sales from competitive fringe. The margin with the dominant retailer, at the same time, does not improve because there are no sales to the dominant retailer in any period except in period 1 in a pricing cycle.

The manufacturer will also have no incentive to lower the wholesale price $w_i$ in any period $i = 2, \ldots, N$. Suppose the manufacturer sets a wholesale price $\tilde{w}_i < w_i$ in period $i$. There will be one of the following two consequences. In the first, the new wholesale price is not low enough, so the dominant retailer will keep selling inventory carried over from period 1, i.e., $\tilde{w}_i \geq w_i + h_1(i - 1)$. Such a decrease will then only decrease the manufacturer’s profit because the margin the manufacturer gets from orders from competitive fringe is smaller, while sales do not change at all. In the second consequence, the new wholesale price makes it more profitable for the dominant retailer to order from the manufacturer in period $i$, i.e., $\tilde{w}_i < w_i + h_1(i - 1)$. This is essentially the same as the case where the manufacturer restarts a new pricing cycle. As shown above that it is not optimal for the manufacturer to deviate from the preannounced $N$ to any $N < N$, the manufacturer will not decrease the wholesale price from $w_i$ to any $\tilde{w}_i < w_i + h_1(i - 1)$ in period $i = 2, \ldots, N$.

Therefore, the manufacturer’s announcements of both the length of pricing cycle $N$ and the sequence of wholesale prices $w_i$, $i = 1, \ldots, N$, are credible and self-enforcing. □
